

Seminar 1

Data Storage Paradigms, IV1351

20/11/2025

Project members:

[Johannes Ahlman, jahlma@kth.se]

[Emil Andersson Hagborg, emiah@kth.se]

Declaration:

By submitting this assignment, it is hereby declared that all group members listed above have contributed to the solution. It is also declared that all project members fully understand all parts of the final solution and can explain it upon request. It is furthermore declared that the solution below is a contribution by the project members only, and specifically that no part of the solution has been copied from any other source (except for lecture slides at the course IV1351), no part of the solution has been provided by someone not listed as a project member above, and no part of the solution has been generated by a system.

1 Introduction

This report is about creating a database for a university following a conceptual model provided in the task. The task itself contains two parts, the first with focus on creating a model and the database itself. The second more managing different special cases such as not allowing more than four distinct course instances at a time for an employee and being able to add more versions of the same layout.

2 Literature Study

To solve the task the main knowledge surrounds creating a logical and a physical model from the conceptual model. The conceptual model itself is a tool for us to understand what the system should look like and it especially gives a good understanding of what we need to include in the future design. By creating a logical model we will provide

tables, relations and keys. By creating a logical model we see how we should build the database. By creating a physical model we provide the more technical aspects of the table, such as data types and constraints. For the task provided in this seminar we use a model that works like a hybrid of both named models. To try and confirm that our database later holds the correct data and is effective we use normalisation.

3 Method

This chapter tells *how* you solved the task. Explain how you worked when solving the tasks and how you evaluated that your solution met the requirements. *Do not explain your solution and do not refer to code*, that belongs to the *Result* chapter. More specific instructions for the content can be found under each task on the Project page in Canvas.

4 Result

This chapter explains *the result* of what you did. The report must show that you have done the work yourself and that you have understood what you have done, both of these goals are met by carefully explaining your solution here in the result chapter, and proving that it meets the requirements. *State each requirement that is met* and explain *how you met it*. Also include links to your code in your Git repository, and include also diagrams, see Figure 1, and other figures to illustrate your reasoning. All figures must be referenced in the text. Ask yourself if the solution is clearly explained, and if the reader will understand the application. What would you yourself want to know if you read about the application, is that included in the report? More specific instructions for the content can be found under each task on the Project page in Canvas.

Figure 1: A sample diagram, included to illustrate caption (this text), numbering and reference in text.

5 Discussion

This chapter *analysis* the result presented in the previous section. Evaluate your solution according to the assessment criteria found in the assessment-criteria documents, which are found under the bullet *In the Discussion chapter of your report...*, under each task on the Project page in Canvas. You do not have to cover all specified criteria.
